Epilepsia partialis continua is a rare type of brain disorder in which a patient experiences recurrent motor epileptic seizures that are focal (hands and arms in this particular case). This condition is often referred to as Kojevnikov's epilepsy or Epilepsia partialis continua (EPC) for short. It is characterized by continuous, regular or irregular clonic muscular twitching of the affected limbs.

Causes of Epilepsia partialis continua can include brain tumours, cerebral infarction, and encephalitis. In some cases, the disorder may develop late in life, and the underlying causes can range from brain tumours to cerebral infarction or encephalitis.

The condition is often diagnosed through a combination of clinical examination, medical history, and imaging studies. Treatment options may include medication, surgery, or a combination of both. The goal of treatment is to control seizures and improve quality of life for the patient.

Epilepsia partialis continua is a rare condition, and its prevalence varies depending on the geographical location and specific population. It is likely that the exact number of cases is unknown due to the rarity of the condition.

In conclusion, Epilepsia partialis continua is a complex and challenging condition that requires a multidisciplinary approach to diagnosis and management. Early identification and appropriate treatment can significantly improve outcomes for affected individuals.
Epilepsia Partialis Continua Symptoms | Epilepsia Partialis Continua: Symptoms Incidence, Prevalence Riskfactors Laboratory, Imaging ECG Complications and Differential diagnoses on Clinical and physiological features of Summary.
